

The Quantum Threat & The Path to Crypto-Agility

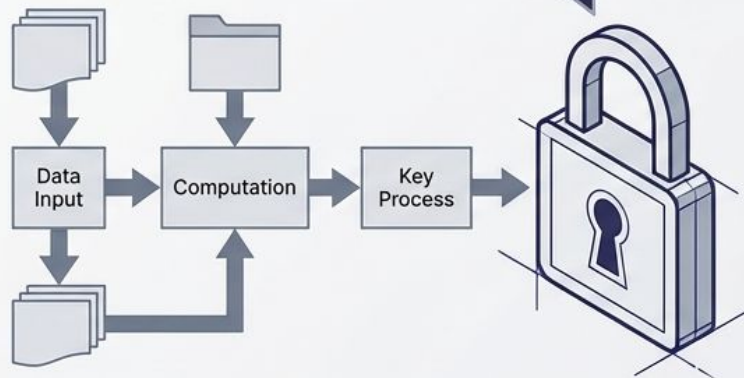

Navigating Harvest Now, Decrypt Later and the
Mandate for Automated Cryptography Discovery

Vince Stoffer - Field CTO Corelight

A Fundamental Leap in Computation

Classical Computing

The Classical Limit: Traditional encryption relies on mathematical problems (like integer factorization) that take classical supercomputers millennia to solve.

Quantum Computing

The Quantum Reality: Leveraging superposition, a Cryptographically Relevant Quantum Computer (CRQC) can solve these exact problems in hours.

The Threat: Shor's Algorithm completely breaks modern public-key cryptography.

The Cryptographic Fault Line

Classical Asymmetric (RSA, ECC, Diffie-Hellman)	Classical Symmetric (AES-128)	Post-Quantum Cryptography (Lattice-based ML-KEM / Hash-based LMS)
Underlying Math: Integer factorization / Discrete logarithms.	Underlying Math: Key length.	Underlying Math: Structured lattices / Cryptographic hash functions.
CRITICAL VULNERABILITY	MODERATE VULNERABILITY	SECURE
Broken entirely by Shor's Algorithm.	Grover's Algorithm halves key strength. Requires immediate upgrade to AES-256.	Immune to known quantum algorithms.

The Vulnerability Window is Already Open

PQC
Deployment
Date

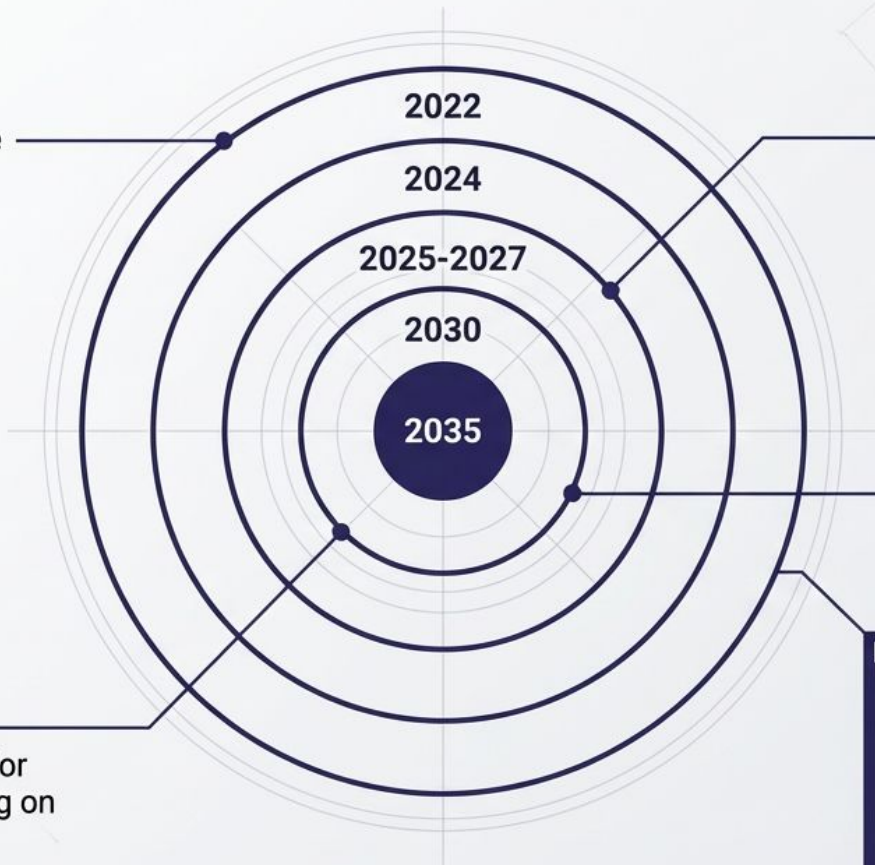

= Q-Day minus
Cover
Time

The Threat to Longevity: Any data with a shelf-life extending beyond Q-Day (state secrets, intellectual property, health records) is already compromised if traveling over classical encryption.

The Mandate for Quantum-Resistance

2022 (NSM-10): White House directive requires federal agencies to inventory vulnerable systems.

2024 (NIST FIPS 203/204): Finalized Post-Quantum algorithms officially published.

2030: Recommended full deprecation of RSA/ECC algorithms.

2025-2027 (CNSA 2.0): Mandatory transition begins for software and firmware signing on National Security Systems.

Financial Impact: The U.S. government estimates a \$7.1 Billion transition cost for non-National Security Systems alone.

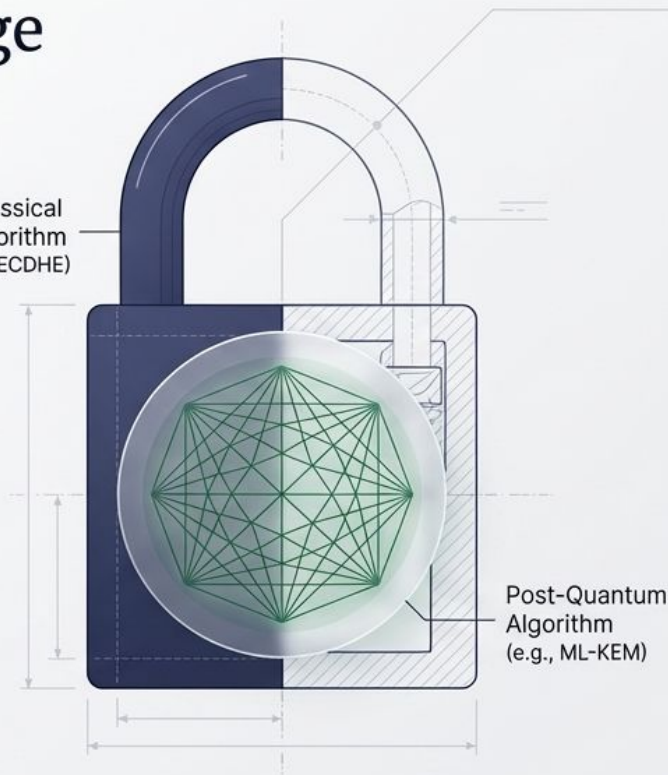

Bridging the Gap with Hybrid Key Exchange

The Strategy

Combine a traditional algorithm with a post-quantum algorithm within the same TLS 1.3 handshake.

An attacker must break both to access the payload.

Classical Algorithm
(e.g., ECDHE)

Post-Quantum Algorithm
(e.g., ML-KEM)

The Outcome

Protects against HNDL attacks today, while hedging against any undiscovered mathematical flaws in newly standardized PQC algorithms.

You Cannot Protect What You Cannot See

The transition to Post-Quantum Cryptography is a massive inventory challenge. Before migrating to quantum-safe algorithms, an enterprise must answer one impossible question: Where exactly is RSA-2048 running in our network right now?

The Foundation of Crypto-Agility: The CBOM

```
{
  "CBOM_Inventory": [
    {
      "Asset": "Server_Certificate_A",
      "Algorithm": "RSA-2048",
      "Key_Length": "256",
      "Status": "Deprecated",
      "Cipher_Suite": "TLS 1.2"
    },
    {
      "Asset": "Encryption_Key_B",
      "Algorithm": "AES-GCM",
      "Key_Length": "256",
      "Cipher_Suite": "TLS 1.3"
    },
    {
      "Asset": "Signing_Key_C",
      "Algorithm": "ECDSA_P256",
      "Key_Length": "256",
      "Cipher_Suite": "N/A"
    },
    {
      "Asset": "Legacy_System_D",
      "Algorithm": "SHA-1",
      "Key_Length": "160",
      "Status": "Deprecated",
      "Cipher_Suite": "N/A"
    }
  ]
}
```

Definition

A Cryptographic Bill of Materials (CBOM) catalogs every cryptographic asset—algorithms, key lengths, certificates, and cipher suites—actively in use across the environment.

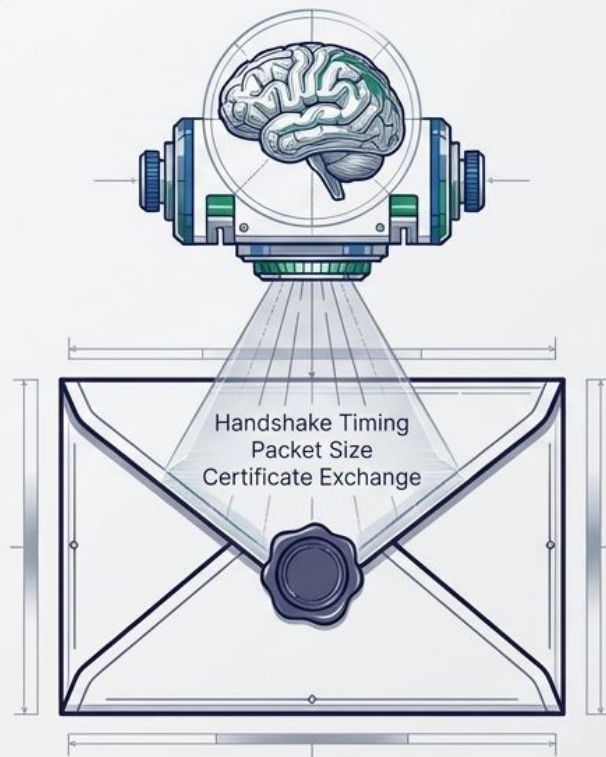

Purpose

A dynamic CBOM is the mandatory first step outlined by federal mandates (like NSM-10) to baseline current risk, identify deprecated algorithms, and prioritize the **PQC migration**.

Total Insight, Without the Overhead of Decryption

Mechanism

NDR platforms utilize Deep Packet Inspection (DPI) and Encrypted Traffic Analysis to scan the exterior of the connection (unencrypted metadata).

Result

Maps all RFC ciphers, elliptic curves, and certificates in real-time.

Achieves 100% cryptographic visibility.

Achieves 100% cryptographic visibility without breaking data privacy or impacting performance.

Building the Automated CBOM Pipeline

Gather

Passive collection of network and cloud traffic at scale.

Analyze

Extract SSL/TLS metadata, categorize services, and map cryptographic capabilities (DPI for PQC-enabled protocols).

Attribute

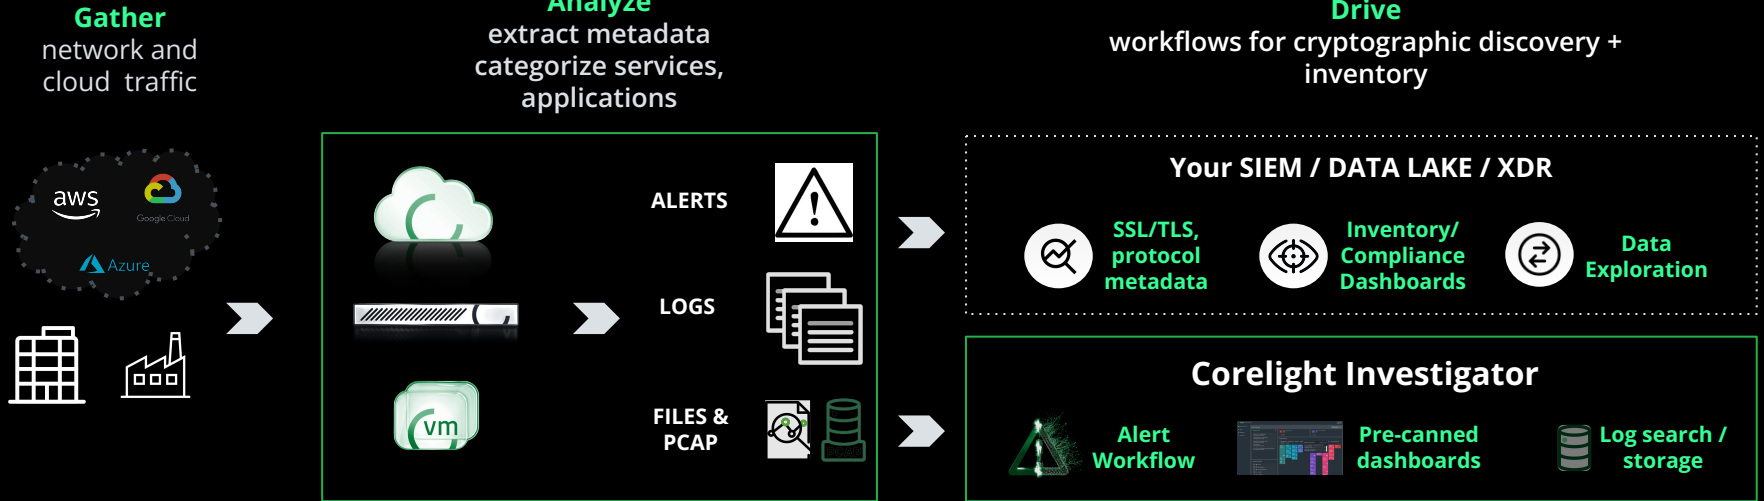

Correlate crypto data to specific applications, unmanaged devices, and users using entity profiling.

Drive

Export structured data to SIEM/Data Lakes to power continuous PQC Readiness Dashboards.

Corelight Open NDR | Powerful network data generation for ACDI

Deploy physical, virtual, software, cloud, at scale

Can operate fully air gapped

- DPI for PQC-enabled protocols
- Full metadata extraction for SSL/TLS
- Capture crypto capabilities exchange as well as chosen ciphers
- Maps all RFC ciphers/curves
- Powerful protocol, service, and application discovery
- Works across all ports (DPD)

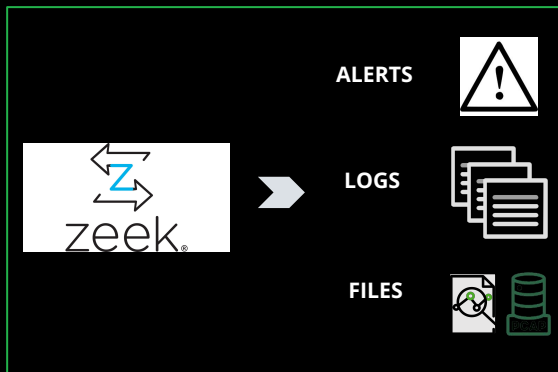

- Flexible export for integration with existing SIEM/analytics workflows
- Compact data for long-term storage and inventory
- Easy to create dashboards and feed other inventory systems
- Unique connection identification to tie application/service to crypto data

Client IP

Server IP

Protocol,
Service and
application

connection details

- Basic connection metadata + protocol, service, and application information
- Use to generate inventory information using IP, port, service and other details
- Protocol and services are identified regardless of port based on dynamic protocol detection (DPD)
- Unique identifier (UID) ties to other logs including protocol specifics

Future needs from Zeek

- Improvements to identification (translation of numerical identifier to human readable name) of PQC cipher suites and curves
- Faster and/or dynamic input for PQC cipher suites and curves
- Exploration of additional log enhancements and additions to facilitate specific protocol requirements (i.e. what else can we find?)
- Exploration of TLS 1.3 / ECH implications on ACIDI

Q & A
